Information

Use Lab3 database

Convert the given ER model into a Relational Model and implement the following constraints along with those shown in the ER diagram.

Constraints:

- Every Publisher must have a Firstname and a Surname. Country information can be missing for some records.
- The AuthorName can be NULL.
- An author can be a mentor to another author
- An author may not have a mentor and cannot have more than one mentor.
- A mentor can have many mentees, but at least one is required.
- Every Email is unique
- An Email must contain '@' and '.' and cannot contain any blank space. It must contain at least one character before and after '@' and '.'
- The book price can be NULL, but not a negative number or zero.
- Every book must have a title.
- If any record is deleted or updated, decide the corresponding action to be taken on related tables/columns.

Hint: Unary relationships can be implemented either using a self-referencing foreign key or by a separate relationship table. The self-referencing approach is suitable for One-to-one and One-to-many relationships, whereas a separate table is preferred for many-to-many relationships or when the relationship has attributes.

The diagram is a hand-drawn Entity-Relationship (ER) model. It features four main entities: Publishers, Books, Authors, and a self-referencing relationship for Authors. Publishers has attributes Firstname, Surname, Name (underlined), and Country. Books has attributes BookID (underlined), Title, and Price. Authors has attributes AuthorID (underlined), AuthorName, and Email (underlined). There is a 'Publishes' relationship between Publishers and Books. A 'Collaborates' relationship exists between Publishers and Authors. A 'Mentorship' relationship is shown as a self-referencing relationship on the Authors entity, with 'Mentor' and 'Mentee' roles indicated by arrows pointing to the relationship diamond.
